DayJournal user manual

DayJournal browses a day journal: a directory with snapshots of day and week charts. It reads the words written on each image to make tags you can search, keeps notes for each image, and lets you draw on them. See DESIGN.md for how it is built.

Opening a journal

At start DayJournal opens the journal used last. The first time, it opens the first `DayJournal*` directory in `/u/trade` (or `~/u/trade`). When there is no `/u` or `~/u` directory, it looks in `trade` in your documents directory (`~/Documents/trade` on macOS, `Documents\trade` on Windows), and in the documents directory itself. **Open** picks another directory, and its drop down lists the recent journals and the ones found there. Journals in temporary directories (`/tmp`, or `/var/folders` on macOS) are not kept as recent ones.

File ▸ New Window (⌥⌘N) opens another window on the same journal and image. Use it to look at two images at once, or open another journal in it. Each window has its own search, list and drawings; notes and drawings saved in one show up in the others on the same journal. **Quit** closes them all. The **Window** button in the toolbar does the same.

Window arranges the windows shown on the screen of the one you are in, which goes first:

Entry	What it does
Minimize (⌘M)	minimizes this window
Tile (⌥⌘T)	all the windows as a mosaic: two side by side, three with one wide below, four in a 2×2 grid, and so on
Side by Side	all the windows in columns
Stacked	all the windows in rows
Main on the Left	this window on the left half, the others one over the other on the right
Main on Top	this window on the top half, the others side by side below
Cascade	all the windows a bit apart, one over the other
Fill the Screen, Left Half, Right Half, Top Half, Bottom Half, Center	this window alone

At the end it lists the windows shown, to bring one to the front. The other windows keep more or less their order on the screen. A window that can't get as small as its place keeps its smallest size and stays on the screen.

Images are found by their names: `day261014.png` for a day, `day261014b.png` for another chart of that day, and `day261011weekprof.png` for a week profile. A week profile dated a Sunday (11 Oct) is for the week that starts the next day (Monday 12 Oct); one dated another day is for the week of that day. Other files are left alone. New images are picked up as they are saved into the directory; **Reload** (⌘R, F5 elsewhere) looks again.

Adding captures

Drop a capture (a PNG, JPEG or other image) anywhere on the window, or use **File ▸ Add Capture…** (⌘I), to add it to the journal. A window shows the capture and asks for its date:

- At first the date is the day the file was last changed. Meanwhile the OCR reads the dates written in the image (`mié 26-10-14`, `14/10/2026`, `29 sept 2026`…), and when it is done it proposes the last one that isn't after the day the file was changed (charts show the days before too), or that day when all of them are after it. If the image has a Sunday and the Friday after it, it is taken as the week profile of that Sunday.
- **Week profile** starts checked when the date proposed is a Saturday or Sunday (the profile is then named on that Sunday), and unchecked for any other day. Check or uncheck it to change it; a week profile is named on the Sunday before its week.
- **Dates found** lists the date proposed first, then the other dates in the image, in the order they were found (and how many times), and the day the file was changed. Pick one to use it, or set the date by hand. Picking one sets **Week profile** the same way; you can still change the box afterwards.
- **Saved as** shows the name it gets: the first capture of a day is `day261014.png`, and the next ones `day261014b.png`, `day261014c.png`… Nothing already in the journal is replaced, unless you check the box below.
- **Replace** (unchecked at first, and only there when the day or week already has captures) saves this one as the only capture of that day or week profile, `day261014.png`, instead of adding another. The captures replaced are deleted with their drawings and tags; their notes go to the new one.

Add copies the capture into the journal with that name (as PNG if it was another format), keeps what the OCR read as its tags, and shows it. The dropped file is left where it was. Dropping several captures asks for each one in turn.

Tags

The first time an image is seen, DayJournal reads its text with OCR in the background; the status bar shows how many are left. This takes a few seconds per image, and only happens once: the results are kept in `.pyjou-tags.json` in the journal directory. An image that changes on disk is read again.

Of the text read, the tags are what looks like words. Prices, numbers, dates, short Spanish and English words (*de*, *en*, *the*), letters with no vowels and other OCR noise are dropped; trading terms in capitals (*RTHOG*, *SMT*, *ES*) and time frames (*m15*) are kept. The tags show under the image; click one to search for it.

Edit ▸ Read Tags Again (⌘T) reads the image shown again, and **Read All Tags Again** all of them.

Searching

Type in the search box to show only the images whose tags or notes match:

Search	Images shown
`judas swing`	with both words
`judas | silver`	with either word
`!judas`	without the word
`(silver bullet) | !(EQL EQH)`	parentheses group

Words match tags and whole words of the notes and of the text boxes drawn, ignoring case. A final lowercase `s` is optional, so `EQL` finds *EQLs*, and `*` matches any letters within a word: `EQ*` finds *EQL*, *EQH* and *EQLs*. A wrong search turns red and its tooltip says why. Esc empties the box. **Days** and **Weeks** choose which kind of image is listed.

Aliases

A word can stand for others too. The file `aliases.txt` in the journal directory has a line for each word, the word, `:` and its aliases separated by commas:

```
# news, and the reports that are news
news: NFP, PPI, CPI
FVG: IFVG, gap*
```

Searching `news` then also finds the images with *NFP*, *PPI* or *CPI*; `!news` hides them all. The word and its aliases match as any search word does: ignoring case, with an optional final `s` (`NEWS` and `new` use the same aliases), and `*` within an alias. Aliases go one way only: `CPI` finds just *CPI*, and a search word with `*` has no aliases. `#` starts a comment, and a word with several lines gets all of them.

Edit ▸ Aliases... edits the file and searches again; you can also edit it with any text editor, and the window reads it when the journal reloads. All the windows of a journal share its aliases.

The list

The list groups the images by year, month and week. Weeks start on Monday, and each week profile is listed first in the week it is for. Click a group, or use ←/→ on it, to open or close it. The small triangle above the list opens all the groups, or closes them all when some are open. At start only the last year, month and week are open, and the week before too when the last one has a single day. Moving to an image opens its groups, and a search opens the groups of what it finds. A week that spans two months shows up in both, with the days of each.

Weeks are numbered in calendar weeks from the first one in the journal, which is 1: `5. Week 26 Oct` is the fifth week since then, counting weeks without images too. Another image of a day shows with its letter, as in `Tue 26` and `Tue 26b`. Above the list, the count says how many images are shown, of how many, and how many weeks have images (`12 of 40, 9 weeks`).

Beside the triangle, **m** closes the list down to the months, keeping the last month open with its weeks and the days of its last week, and **w** closes it down to the weeks, keeping the days of the last week.

Double click an image in the list to change its date, or whether it is a week profile. The window is the one used when adding captures, titled *Change Date*, with the dates read in the image. **Change**

renames the image, with its notes, drawings and tags, to the name shown in **Saved as**; keeping the date keeps the name.

To move an image to another day, drag it from the list to that day in the calendar (go to another month with the calendar's arrows first). The day under the image is selected while you drag; dropping renames it, with its notes, drawings and tags, to the next name free for that day. A week profile dropped on any day goes to the week of that day, named on the Sunday before it. Dragging an image to the Finder or to another DayJournal window copies it there.

Right click an image in the list for **Cut**, **Copy** and **Paste** (⌘X, ⌘C and ⌘V work too while the list has the focus). Copy an image, open another journal (or keep this one) and paste: the image is copied there with its notes, drawings and tags, keeping its date. It gets the next name free for that date (`day261014b.png` when `day261014.png` is there), so nothing is overwritten. Cut works the same, but the image leaves its journal when it is pasted, and is shown in gray until then; pasting it in its own journal does nothing. Paste also works between two DayJournal windows, and pasting image files copied in the Finder adds them as captures.

Delete Capture… in the same menu (or Del, or ⌫, while the list has the focus, or **Edit ▸ Delete Capture…**) deletes the image selected with its notes, drawings and tags, and shows the one after it. It asks first; check **Don't ask again** to delete without asking from then on, and turn **Edit ▸ Ask Before Deleting** back on to be asked again. A deleted capture can't be recovered from DayJournal.

Moving around

- Click an image in the list, or use ↑/↓ there.
- With the image focused (click it): ←/→ or ↑/↓ for the previous or next image, Home/End for the first or last, W for the week or day. While writing in a text box the keys go to the text.
- PgUp/PgDown anywhere for the previous or next image, ⌘Home/⌘End for the first and last.
- **Week** (⌘W) goes from a day to the profile of its week, and back to the first day of the week.
- Click a day in the calendar to see it. Days with images are in bold blue, and the ones the search hides are grey; a day without an image goes to the next one that has one.

Searching, the arrows and the calendar move through the images listed.

The image

Fit fits the image in the window, **Real Size** shows it at its size, and **Zoom +**/**Zoom –** zoom. On a trackpad, a double tap with two fingers zooms in, zooms in again, and fits again, keeping the point tapped in place, and pinching zooms in and out. Drag to move around. **View ▸ Open in Preview** opens it with the system viewer.

The cursor is a crosshair: a dashed horizontal and vertical line through the mouse, across the whole image, so you can see the same level or time at other places of the chart. It hides while you draw, drag the image or write a text, and comes back when you move the mouse again. **Cross** on the drawing bar (or X with the image focused) turns it off and on, for DayJournal and RoadBook alike; with it off, the cursor is the hand again when dragging the image.

Copy on the drawing bar (⇧⌘C, **Edit ▸ Copy Image**, or **Copy Image** when you right click an image in the list) copies the image with its drawings to the clipboard, at its own size, to paste it in a message, a document or another program. ⌘C in the list still copies the capture, to paste it in another journal.

The **List** and **Notes** buttons, at the left of the toolbar (**View ▸ Show List**, ⇧⌘L, and **View ▸ Show Notes**, ⇧⌘N) hide and show the panel on the left (the search, the list and the calendar) and the tags and notes under the image, so the image gets the room. The window remembers them. **Search** (⌘F) and **Edit Notes** (⌘N) show their panel again.

Drawing

The buttons above the image, on the left, draw on it: **Pencil** (free hand), **Line**, **Arrow**, **Circle**, **Rect**, **Text** and **Fib**. Pick one and drag on the image (for Text, click where the box goes and type; click elsewhere or press Esc when done). Hold Shift while placing the end of a line or an arrow to keep it horizontal or vertical. With the image focused the keys S, P, L, A, C, R, T and F pick the tools too.

Line, **Arrow** and **Circle** open a window when you double click them, to change their **Color**, **Width** and **Style** (solid, dashed, dotted) and give them a **Label**, with its **Text size** and **Label color**. The label goes **Above**, **Center** (across it; the line stops around the label) or **Below**, and **Left** (at its left end), **Center** (in its middle) or **Right**. For lines and arrows, **Right** puts the label past the right end of the line, kept inside the image.

Rect draws a rectangle, just its border at first. Double click its border (anywhere on it once filled) to set:

- **Fill**, with its color and **Transparency** (0% hides what is under it);
- **Line across the middle**, dashed, with its color;
- **Label** (FVG, OB...), aligned **Center**, **Left** or **Right**, written across the middle of the rectangle (the middle line stops around it), with its **Label color**.

The arrow next to **Rect** picks the kind of rectangle to draw: **Plain** (just the border, in the drawing color) or one already set up, with its colors, fill, middle line and label:

Kind	Looks like
BRK	green border and fill, green middle line
MB	green border and fill, green middle line
FVG	black border, light orange fill, black middle line
IFVG+	orange border and fill, red middle line
IFVG-	blue border, light cyan fill, black middle line

Picking a kind with rectangles selected changes them to it instead.

In these windows the drawing shows each change at once; **Cancel** puts it back as it was.

Fib draws Fibonacci levels. Press on the first point (level 1) and drag to the second one (level 0), or click one and then the other. Then move the mouse and click where the lines end, or double click on the second point to take them to the right edge of the image. While you draw it, a dashed line shows where the second point (level 0) is. Esc or the right button drops a fib not finished. Each level has its number just past the right end of its line, centered on it; lines taken to the edge of the image stop short of it to leave room for the numbers. The arrow next to **Fib** picks the levels:

Set	Levels
OTE (the default)	0.5, 0.62, 0.705, 0.79
Quadrants	0, 0.25, 0.5, 0.75, 1
PO3	the quadrants and −0.5, −1, −1.5, −2, −2.5, 1.5, 2, 2.5, 3, 3.5
Custom…	a form with 20 levels in two columns: check the ones to draw and type their values

The custom form starts with all the levels above, and two blank ones, and remembers what you set. Its **Draw the diagonal** box adds the dashed line from the first point to the second; the other sets never draw it. Picking a set with fibs selected changes their levels instead.

The ⧉ button at the start of the drawing buttons detaches them as a small floating bar that stays on top of every window, so you can keep it where it suits you. Click ⧉ again, or close the bar, to put it back.

Select (the usual tool) clicks a drawing to select it, drags it to move it, and Del or **Delete** removes the ones selected. Shift-click selects more than one. Double click a text box to change its text; emptying it removes it. Dragging the image itself moves around it, as before.

The color button, the width list, the line style list (solid, dashed, dotted) and the text size list (**Aa 16** by default, for text boxes, labels and fib numbers) set how new drawings look, and change the ones selected. **Clear** deletes every drawing on the image; **Undo** brings them back. **Undo** and **Redo** (⌘Z, ⇧⌘Z) undo and redo the drawing changes of the image shown.

Drawings are kept until you **Save** them (⌘S, or the Save button in the toolbar); meanwhile the window title says *(unsaved)*. You can go to other images and draw there too before saving, and Save writes them all. Quitting or opening another journal with unsaved drawings asks whether to save them. They go in a file with the image's name and a `.drw` extension (`day261014.drw`), and saving an image without drawings removes its file. Notes are still saved as you type.

Drawings are kept in image coordinates, so they stay in place when zooming. The words in the text boxes and labels are found by the search, as the notes are.

Notes

Write under the image. Notes are saved as you type, in a file with the image's name and a `.txt` extension (`day261014.txt`). Emptying the notes removes the file. Images with notes have a ✎ in the list, and their notes show in its tooltip.
